

**Machine for volumetric filling of powders****TECHNICAL FIELD**

The present invention relates to a method and a device for filling a  
5 succession of containers with metered doses of finely divided dry medication  
powder, the doses intended for inhalation by means of a dry powder inhaler  
(DPI).

**BACKGROUND**

10 Dosing of drugs is carried out in a number of different ways in the medical  
service today. Within health care there is a growing interest in medical  
products based on administering drugs by inhalation of dry medicament  
powder directly to the airways and lungs of a patient. Interest focuses often  
15 on dry powder inhalers (DPI) because they offer effective, quick and user-  
friendly delivery of many substances formulated as dry powder doses for  
treatment of many different disorders. Because onset is faster and the  
efficacy of inhaled doses often are much higher than e.g. orally administered  
20 capsules or tablets, the inhalation doses need only be a fraction of the  
medicament powder mass in an oral capsule or tablet. Thus, there is an  
increasing demand for relatively low mass, inhalable, metered medicament  
doses, which require better filling methods and devices for making small and  
25 exact inhalation doses with low relative standard deviation (RSD).

Volumetric filling is by far the most common method of producing dry  
25 powder doses of medication drugs. Normally in a first step a quantity of  
powder is introduced into a receptacle of specified volume by gravitation,  
often aided by mechanical energy in the form of impaction or vibration, or  
the receptacle may be filled by suction force. Then in a second step, after  
30 stripping of possible surplus powder, the receptacle is moved to an emptying  
position, where the powder is unloaded from the receptacle by gravitation  
into a container such as a blister or capsule etc. A plurality of receptacles  
may be arranged in some kind of tool, which is adapted to a mechanism

bringing a plurality of containers, e.g. blisters or capsules, in line with corresponding receptacles so that all doses of powder may be unloaded into the containers, one container per dose. The receptacle tool may be integrated into a filling machine such that the receptacles can be filled and emptied in 5 a more or less continuous, cyclic fashion. Examples of prior art may be studied for instance in publications EP 0 319 131 B1, WO 95/21768, US 5,826,633, US 6,267,155 B1, US 6,581,650 B2 and DE 202 09 156 U1.

10 Powders for inhalation need to be finely divided so that the majority by mass of particles in the powder is between 1 and 5  $\mu\text{m}$  in aerodynamic particle size (AD). Powder particles larger than 5  $\mu\text{m}$  tend not to deposit in the lung when inhaled, but to stick in the mouth and upper airways, where they are medicinally wasted and may even cause adverse side effects. However, finely divided powders are rarely free flowing, but are prone to adhere to all 15 surfaces they come in contact with and the small particles tend to aggregate into lumps. This makes the metering of correct doses more difficult, since the bulk density of the powder may vary considerably from dose to dose even if the bulk density is constant when measured on powder quantities several magnitudes larger than the doses. Metering and filling correct quantities into 20 a dose container is therefore more difficult with low dose masses. However, demand for doses from 5 mg down to 0.1 mg is increasing, putting pressure on the industry to improve methods and devices for metering and filling in the manufacturing stage as well as on dry powder inhalers to improve 25 performance in terms of deaggregation and efficacy. Compacting the powder in the metering receptacle to reduce metering errors can be done, but care must be exercised so that agglomeration is not aggravated and to ensure that the agglomerates may still be de-aggregated by the inhaler.

30 Electrostatic forces, friction forces and van der Waal forces acting on particles become stronger than the gravitation force when particle size diminishes. Medication powders are very susceptible to electrostatic

charging during transportation and handling of powders, especially in dry conditions. It is often necessary to remove as much as possible of electric charges of the particles by electric de-charging methods, particularly if the particles are small in size, in order to reduce the tendency of particles to 5 stick to all surfaces of the handling equipment.

There is a need for improvements in methods and devices for precise metering of medicament doses of finely divided powders for inhalation and consistent, reliable filling of doses into suitable containers for use in inhaler 10 devices.

## SUMMARY

The present invention discloses a method and a device for precise, repeatable filling of finely divided dry powder into preformed containers; the container 15 and the contained dose being adapted for inhalation by means of a DPI.

In a preferred embodiment of the invention woven filters are used together with elastic seals and optional supporting wire netting in connection with a multitude of metering receptacles for improving dose metering accuracy and 20 dose forming reliability and for reducing powder retention in the metering receptacles.

In another aspect of the invention a filling tool is disclosed presenting a multitude of metering receptacles where at least the surface in the 25 receptacles and optionally other tool parts are polished and if necessary specially coated to reduce friction and potential wear between the filling tool and associated parts. Appropriate polishing and coating may reduce the amount of powder sticking to the outer surface area of the filling tool during the filling operation and to the receptacle inner walls and other areas of the 30 filling tool after unloading.

In yet another aspect of the invention the metering receptacles may be circular or elliptical cones with circular or oval openings towards the air supply. The elliptical form is preferred, because it may be adapted to fit an 5 elongated, preformed container receiving a load from the conical receptacle, such that the powder load may be deposited onto the intended target area without spillage onto other areas of the container. The elastic seal around the opening in the conical metering receptacle for the air supply ensures a repeatable, leak-free connection between the opening, the filter and an air 10 nozzle for many filling and unloading cycles.

In a further aspect of the invention the shape of the deposited load of powder, which may be a dose, is reduced in height by exposing the load or the load and container to an energy source such that the deposited powder 15 load is reduced in height and distributed reasonably evenly over the available target area in the container before it is sealed, e.g. by foiling. The energy supplied may be mechanical, e.g. ultrasonics, vibration or shock, or electric, e.g. static electricity or from an ac electric field.

20 In yet a further aspect of the invention the powder particles are electrically discharged by applying static charge elimination devices where needed to keep static charging to a minimum of the powder, the filling tool and associated equipment throughout the filling procedure. For instance, bulk powder in a metered load will be electrically discharged, i.e. electrically 25 neutralized, the moment the powder load is unloaded from the metering receptacle. A source of electric charges, e.g. an ion source, may be installed in the gap existing between the tool and the containers, such that emitted electric charges from the ion source are attracted to electrically charged particles in the powder load while it transfers through air. Neutralizing 30 electrically charged particles in this way eliminates particle spillage due to charged particles being electrostatically deflected in the direction of other

objects and surfaces besides the intended target area of the container to be filled.

A volumetric filling method is set forth by the independent claim 1 and  
5 further embodiments are defined by the dependent claims 2 to 11 and a  
filling tool device is set forth by the independent claim 12 and further  
embodiments are defined by the dependent claims 13 to 22.

#### BRIEF DESCRIPTION OF THE DRAWINGS

10 The invention, together with further objects and advantages thereof, may  
best be understood by referring to the following detailed description taken  
together with the accompanying drawings, in which:

15 FIG. 1 illustrates in a flow diagram the filling method of the present  
invention;

FIG. 2 (a) illustrates an embodiment of the filling tool and (b) illustrates  
an enlarged view of a conical receptacle;

20 FIG. 3 (a) illustrates in principle a longitudinal section of an embodiment  
of the filling tool, (b) a cross section of the filling tool, (c) an  
enlarged view of cross section B and (d) an enlarged view of cross  
section A;

25 FIG. 4 illustrates in principle a longitudinal section of an embodiment of  
the filling tool together with the woven filter, the seals, the air  
nozzles, the air supply lines and the relative positions of the tool,  
the powder in a storage chamber with powder release chutes and  
the containers to be filled, and

FIG. 5 illustrates in an enlarged view a cross section of a receptacle, seals, filter, optional wire netting and air nozzle;

## DESCRIPTION OF THE INVENTION

5 The present invention discloses a method and a device for exact metering and volumetric filling of finely divided dry powder medicament doses into preformed containers, where the doses and containers are adapted for administration by inhalation using a dry powder inhaler (DPI). The method according to the present invention is illustrated in a flow diagram in Figure  
10 1.

In the context of the invention the term "container" is used generically and includes well-known designs such as blisters, capsules as well as bowls and pods, into which a metered quantity of dry powder medicament, a dose, may  
15 be deposited and sealed later to be made available in a DPI, which may deliver the dose as needed to a user inhaling through the DPI device. The term "receptacle" is used to describe a carefully made, truncated, conical cavity of very exact dimensions and volume - machined or otherwise made - into the outer surface of a filling tool, which may have more than one such  
20 cavity on its outer surfaces. From inside the tool access can be made to the smaller end of the conical cavity or cavities to allow fitting of filters and air supply nozzles, which will be described later.

Volumetric filling machines for dry powders in prior art are not easily  
25 adapted to metering and unloading of small doses, especially if the powder is finely divided presenting in the order of 90 % by mass of particles with aerodynamic diameter between 1 and 5  $\mu\text{m}$ . Gravitation in combination with impaction and vibration are popular prior art methods of first filling a receptacle and then unloading the powder collected in the receptacle into a  
30 selected container. Alternative methods and devices involving vacuum and air pressure to collect powder and fill it into targeted containers generally

present better performance in terms of consistency and dose RSD compared to gravitation methods, especially when producing a dose of relatively small mass of powder particles less than 10 µm aerodynamic diameter. Excipients are commonly added to medicaments for different purposes, one of which is 5 to dilute a potent medicament, another is to improve powder flowability.

A device according to the present invention is illustrated in Figures 2 - 5. Figure 2 illustrates a filling tool **100** including four sets **101**, **102**, **103**, **104** of eight receptacles **10** each. An enlarged top view 2(b) of a conical receptacle 10 **10** is also illustrated showing a first **11** and a second **12** opening. The illustrated filling tool is a cylinder, but a different shape would also be possible, e.g. a part cylinder or a polygonal cross-section. The number of receptacles **10** in the tool **100** may vary depending on what capacity is required from the tool. The shape and size of a receptacle may vary 15 depending on the size and mass of the powder load to be metered. The conical shape may be circular or elliptical, the wideness and depth, i.e. the volume, must be adapted to the intended load and the filling and unloading methods.

20 Figure 3 illustrates in 3(a) a cross-section **A-A** and in 3(b) a cross section **B-B** of the filling tool. Enlarged cross-sections **A** 3(d) and **B** 3(c) of a receptacle **10** are also shown.

25 Figure 4 illustrates a stylized, principal drawing of the operational filling tool **100** in a longitudinal cross-section together with a typical storage chamber **110** positioned above and in close proximity to the filling tool, a simple chute arrangement **111** for releasing powder **1** from the storage chamber to each individual receptacle **10** in set **101**. A multitude of containers **130** are positioned beneath receptacles **10** of set **103** and just ejected loads **131** are 30 in the air on their way to their respective containers. Also shown are flexible

seals **105**, woven filters **106**, air nozzles **13** and connecting air lines **112** and **113** for suction **114** during filling and air pressure **115** during unloading, respectively. Separate airlines are shown in the embodiment to simplify the reader's understanding of the principle, but in practice the same 5 air line may be used alternately for suction and pressure during a complete sequence of filling and unloading.

Figure 5 illustrates a stylized, principal, cross-sectional drawing of a receptacle **10**, seals **105**, woven filter **106**, air nozzle **13** and optional wire netting **107** on one of the two or both sides of the filter in order to support it, if deemed necessary. Suction **114** and pressure **115** are also symbolically 10 illustrated.

A filter is necessary when using air to attract or repel powder. A well- 15 balanced suction force applied to a receptacle will attract available, nearby powder and will fill up the receptacle, such that the powder is compacted to a certain degree in the receptacle acting as a metering chamber. The filter at the bottom of the receptacle stops powder from being sucked into the air system and thereby becoming lost in the filling process. The filter is also 20 necessary when air pressure is used to push the load out of the receptacle during the unloading operation, because it will stop possible foreign particles in the air supply system from contaminating the powder in the load. The filter should not be made of felt, because felt material may give off fibers, which may contaminate the powder load. Felt filters are usually rather thick 25 and the fibers in the felt are not held in place by design; the felt is just a compressed collection of fibers, randomly arranged and held together by a bonding agent and a more or less loose fabric. In use the felt will let go of fibers, which may mix into the powder and follow the powder load into the container. The present invention preferably uses a woven, pre-stretched, 30 surface-treated thin filter manufactured by W.L. Gore & Associates, Inc. of Newark Delaware, which by design cannot lose fibers to air passing through.

A further advantage of the invention is that the filter is so thin that it is easily sealed to the air connection end of the metering receptacle. Instead of common prior art practice of squeezing the felt filter tight to the receptacle by mechanical high force deforming the thick felt, the stretched woven filter 5 is held in place by an elastic seal, which seals the filter to the bottom end of the receptacle, preferably using an arrangement comprising a resilient, moderate spring force acting on the air nozzle on the other side of the seal, whereby the contact pressure is kept constant, thus maintaining a tight connection between the air nozzle and the air connection end of the 10 receptacle. The seals should be non-fibrous and may be made of e.g. PTFE, PFA, EPDM, Neoprene or Nitril and similar, medically approved materials. A further advantage of the invention is that the woven filter requires much less differential pressure across it compared to a felt filter for a given flow and 15 particle filtration, i.e. less energy is needed, which simplifies control of the filling and unloading operations.

Proper metering of the powder quantity in the receptacle is difficult but important and consistency between loads out of the same receptacle is of course also important and so is consistency between loads from different 20 receptacles in the same tool, if there are more than one. A prior art felt filter is easily deformed when it is squeezed tight to the air connection end of a receptacle, e.g. by pushing an air nozzle with considerable force into the felt. The felt will bulge inwards and intrude into the bottom of the metering receptacle, thus reducing the actual volume in the receptacle, which in turn 25 reduces the powder load sucked into the receptacle in the filling step and results in lower powder mass in the load to be transferred to a receiving container. The present invention solves this problem by using a pre-stretched, woven filter, which is not deformed by the moderate force needed to tighten the filter to the air connection end and it neither intrudes into the 30 receptacle nor expands in the other direction, whereby the volume of the receptacle remains unaffected. Optionally a supporting wire netting may be

used, if deemed necessary, to support the filter on one or both sides of the filter. The result is not only a reduced relative standard deviation (RSD) between subsequent loads from the same receptacle but also less RSD between loads from different receptacles. Of course a metered dose in a 5 container may comprise more than one load, but this is by exception and not the normal procedure, because it takes longer time.

Each receptacle is lined up with and connected to a nozzle, which in turn is connected to a supply of vacuum and compressed air through at least one 10 fast acting on-off valve. For the sake of simplicity, the valve(s) may be common to all nozzles. Filling the receptacles is accomplished by making powder available to the receptacles, e.g. through a chute arrangement from a storage chamber, such as a trough or a hopper. Normally powder is fed by gravitation, optionally aided by addition of energy, e.g. by vibrating the 15 trough. When the tool containing the receptacle(s) has brought at least one receptacle in position to be filled, by opening of at least one valve, suction is applied from a vacuum source to the respective air nozzle, which in turn sucks powder and compacts the load to a degree into the corresponding receptacle. The woven filter stops powder from entering the nozzle. After 20 completing filling of some or all receptacles of the filling tool, the tool is cleaned from surplus powder and moved to a downward pointing position for unloading the load of at least one receptacle into a selected container. When a valve opens, a pulse of compressed air is led through at least one nozzle and filter to the at least one receptacle, where the air exerts a force on the 25 powder load in the receptacle. The load will be ejected from the receptacle and will drop into a selected container, provided it is in correct position. If the tool contains a plurality of receptacles it is advantageous to control the channeling of compressed air to the receptacles one by one in turn. In doing so the risk of dropping air pressure during unloading is eliminated, which 30 may otherwise cause problems if the air pulse is channelled simultaneously to all receptacles, since the individual loads are unlikely to leave their

respective receptacles at exactly the same moment. This problem of synchronization may lead to higher powder retention in some receptacles, which are late in releasing their loads.

- 5 Surprisingly, it has been found that the retention of powder in the metering receptacle after unloading is less when using the woven filter compared to the felt ditto. The reason for this is that because the felt filter of prior art becomes quite deformed and quite dense around the edges, where it is kept tight to the air connection end, pressurized air may only pass through with
- 10 great difficulty near the inner wall of the receptacle during the ejection of the load. This phenomenon leads to a substantially reduced air stream near the receptacle inner wall with insufficient turbulence to clean out all of the powder adhering to the wall. However, even when the woven filter is used instead of the felt filter the cone angle of the receptacle should not be too
- 15 great, otherwise there is a risk that powder retention on the inner walls of the receptacle increases due to insufficient air turbulence near the wall.

Reducing powder retention on all surfaces that may come in contact with powder is a further aspect of the present invention. The material of the filling 20 tool must be carefully selected to present extreme stability of form, good machining properties, good resistance to abrasion, high surface finish with low friction properties, if necessary achieved by coating. Suitable materials for the filling tool include for instance vacuum-arc-remelted (VAR) stainless steel, metals, alloys and glass. Suitable coating materials may be selected 25 from thermoplastic materials, such as PTFE, PE, parylene and similar. The tool surfaces in contact with powder, e.g. the metering receptacles, should be polished or coated to a fineness modulus of less than  $R_a=0.25 \mu\text{m}$ , and preferably less than  $R_a=0.1 \mu\text{m}$  and the resulting surface should present as low dynamic friction coefficient as possible. A preferred embodiment of the 30 filling tool uses a machined stainless steel body, which is ground in several steps and then optionally electro-polished, which results in a fineness of less

than  $R_a=0.1 \mu\text{m}$ . The filling tool may then be metallurgically coated by vapour deposition of e.g. chromium nitride, coal/chrome-combination or graphitic coating. This will ensure a durable filling tool surface with very low friction, making it easy to remove sticking powder particles. Naturally, 5 consideration must be paid to the type of medicament powder and powder formulation in deciding what materials to use for the filling tool, the appropriate grinding and polishing steps and type of coating, if needed.

Electrostatics is often a problem in handling of dry powders, especially finely 10 divided powders. Fine particles are easily triboelectrically charged when transported, not only by contact with objects of the transportation system but also by flowing air. The problem is aggravated by the necessity of handling the powder in a dry atmosphere, typically below 20 % relative 15 humidity, in order not to affect the quality and properties of the powder. The powder particles may be electrically discharged by applying static elimination devices, e.g. from NRD LLC, Grand Island, New York, where 20 needed to keep static charging of the powder, the filling tool and associated equipment to a minimum throughout the filling procedure. By doing so loss of particles due to particle-sticking and other interference from statics with the filling process are kept to a minimum. When an applied air pressure pulse unloads the powder load from the metering receptacle, the powder 25 particles must pass an existing air gap before reaching a receiving container. By triboelectric charging, particles acquire a positive or negative charge to a higher or lesser extent. This electric charge makes them disposed by the influence of stray electric fields, existing in the air gap, to deflect in other 30 directions than the expected inertial and gravitational track and thus settle onto other surface areas than the expected target area of the receiving container. To reduce spillage of this sort the present invention discloses the addition of a source of neutralizing charges, e.g. an ion source, to be positioned near the air gap between the tool incorporating metering receptacle(s) and the container(s). Electrically charged particles will then

very quickly be neutralized by charges from the source and the loss of particles in transfer from receptacle to container due to electrostatics will be reduced.

- 5 When the powder load from the receptacle has been deposited in the container it may be necessary to spread the powder load more evenly over the available area inside the still open container, if the deposit has developed powder peaks. The peaks may interfere with a sealing cover, e.g. a foil to be applied on top of the container in order to seal the container in a next step.
- 10 Spreading the powder may be accomplished in many ways, but preferably without means that presume contact between means and powder, e.g. scrapers. Preferred embodiments of spreading means include a vibrating or shock arrangement to jar the container, or ultrasonics to upset the powder so that powder peaks will collapse and not interfere with the seal being put
- 15 onto the container in an ensuing step.

The present invention relates to consistent filling of dry powder doses of medicament into containers destined for insertion into a DPI, where the pre-metered doses are in a range 100  $\mu$ g - 50 mg and preferably in a range 100  $\mu$ g - 10 mg and most preferably in a range 100  $\mu$ g - 5 mg and presenting an RSD of 5 % or less.

What has been said in the foregoing is by example only and many variations to the disclosed embodiments may be obvious to a person of ordinary skill in the art, without departing from the spirit and scope of the invention as defined in the appended claims.
